Abstract. The interaction of remifentanil with glutamate systems has an important role in remifentanil-induced thermal and mechanical hyperalgesia. A previous study by our group suggested that the trafficking and function of glutamate receptor 1 (GluR1) subunits contributes to remifentanil-induced hyperalgesia by regulating the phosphorylation of GluR1 in dorsal horn neurons. The present study demonstrated that δ opioid receptor (DOR) inhibition prevented thermal and mechanical hyperalgesia, which was induced by remifentanil infusion via attenuating GluR1 subunit trafficking and α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPA) function in dorsal horn neurons. Sprague Dawley rats received a plantar incision and remifentanil infusion led to upregulation of membrane expression of the AMPAR subunit GluR1 and DOR (P=0.003 and 0.001, respectively) no change in total GluR1 and DOR expression levels (P=0.244 and 0.531, respectively). Selective DOR inhibitor naltrindole caused a reduction of remifentanil-induced hyperalgesia, which was accompanied by downregulation of membrane levels of GluR1 in the spinal cord (P=0.0013). In addition, DOR inhibition led to downregulation of GluR1 phosphorylated at Ser845. Furthermore, the AMPAR-mediated miniature excitatory post-synaptic current was increased in frequency and in amplitude in dorsal horn neurons (P=0.002 and 0.0011, respectively), which was decreased by incubation with naltrindole. Combined behavioral, western blot and electrophysiological evidence indicated that remifentanil-induced hyperalgesia was mediated by DOR activation, followed by phosphorylation-dependent GluR1 trafficking and AMPAR function enhancement in the spinal cord. DOR appears to be required for remifentanil and incision-induced hyperalgesia development and to be a potential biochemical target for treating opioid-induced postoperative hyperalgesia.

Introduction

Opioids are considered to be the most effective painkillers for acute, chronic and cancer pain in humans (1). Although opioids provide pain reduction, numerous clinical and experimental studies have demonstrated that opioid intake may increase the risk of persistent pain and pain sensitivity. This phenomenon is known as opioid-induced hyperalgesia (OIH) and often appears after long-term opioid use (2). However, remifentanil is a short-acting μ-opioid receptor (MOR) agonist, which is widely used for the management of postoperative pain (3). In the central nervous system, the excitatory transmission of glutamatergic neurons is mediated by ion flow through α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPA). Several studies have demonstrated that AMPAR antagonists produced an anti-hyperalgesia effect, suggesting that AMPAR has an important role in postoperative pain (5-8). AMPARs are multimeric ion channels composed of...
four subunits, glutamate receptor 1-4 (GluR1-4). It has been reported that the function of AMPARs, which is dependent on its trafficking and conduction, is determined by the composition of AMPAR subunits (9). In the dorsal horn region of the spinal cord, AMPARs principally consist of GluR1 and GluR2 subunits (10). It was reported that GluR1-containing AMPARs are permeable to Ca²⁺ and that the trafficking of GluR1-containing AMPAR into synapses contributes to the formation of long-term potential (11). However, GluR2-containing AMPARs have little Ca²⁺ permeability. Synaptic strengthening is determined by the GluR1/GluR2 ratio in dorsal horn neurons (12,13). In an inflammatory pain model, the composition of AMPAR was changed, accompanied with an increased GluR1/GluR2 ratio and a greater Ca²⁺ permeability (14,15). It has been reported that opioid exposure modified the trafficking of the GluR1 subunit but not of the GluR2 subunit in dendrites of mouse neurons (16). Phosphorylation of the Ser831 and Ser845 sites of GluR1 is essential for the function and trafficking of AMPAR (17).

The opioid receptor family modulates nociception through three G-protein coupled receptors, including MOR, δ-opioid receptor (DOR) and κ-opioid receptor (KOR) (18). DORs are widely expressed in the neurons of the spinal cord dorsal horn, as well as in the dorsal root ganglia (DRG). Several studies suggested that the effects of DOR agonists are more potent than those of MOR and KOR in neuropathic pain. Peripheral nerve injury was reported to upregulate DOR expression in small and large DRG neurons (19). However, DOR protein expression was decreased in the spinal cord of a rat model of inflammatory pain (20). Furthermore, it was reported that the plasma membrane DOR was increased in response to long-term morphine, ATP or capsaicin exposure and chronic neuropathic pain (21-23). Therefore, membrane expression of DOR has an important role in DOR function and the pain process. Previous studies have indicated that DOR inhibition significantly decreased remifentanil-induced hyperalgesia via modulating membrane trafficking and N-methyl-D-aspartate receptors in the dorsal horn, indicating that naltrindole may be an anti-hyperalgesia agent for treating OIH (24). However, the role of DOR-AMPAR in remifentanil-induced hyperalgesia remains equivocal.

The present study assessed whether remifentanil-induced hyperalgesia was accompanied by dysregulation of DOR and AMPAR in dorsal horn neurons. It was determined whether enhancing DOR function was capable of promoting the expression of AMPAR to induce hyperalgesia in rats. It was further investigated whether DOR inhibition was able to alleviate remifentanil-induced hyperalgesia. In addition, the whole-cell patch-clamp assay was used to investigate whether the effect of remifentanil on AMPAR function is mediated by DOR.

Materials and methods

Ethics statement. All protocols and procedures adhered to the Institutional Animal Care Committee of Tianjin Medical University in line with the National Institutes of Health Guide for the Care and Use of Laboratory Animals. The protocols and procedures were approved by the Committee on the Ethics of Experiments of Tianjin Medical University (Tianjin, China; permit no. 2014-X62-27) and the Institutional Animal Care Committee of Tianjin Medical University (Tianjin, China). All procedures were performed under sevoflurane anesthesia and considerable efforts were made to minimize animal suffering.

Animals. A total of 72 male Sprague Dawley (SD) rats (age, 8-9 weeks; weight, 250-280 g) and 24 male SD rat pups (age, 14-21 days; weight, 50-70 g), were provided by the Laboratory Animal Center of the Military Medical Sciences Academy of the Chinese PLA (Beijing, China). Rats were housed in cages with a 12-h light/dark cycle at a temperature of 22±2°C. Rats had access to water and food ad libitum.

Intrathecal catheter placement. An intrathecal catheter implantation was performed as described by Yaksh and Rudy (25). After being anesthetized by sevoflurane inhalation (3.0% for induction, 1.0% for maintenance; Abbott Japan Co., Ltd., Tokyo, Japan), the rats were implanted with 8.5 cm polyethylene (PE-10) catheters via the atlantooccipital membrane down to the lumbar enlargement at L1-L2 of the spinal bony structure. The level of the L1-L2 spinal bony structure corresponds to the spinal cord segments of L5-S3, which are responsible for hind limb pain. The presence of the catheter in the subarachnoid space was confirmed at 24 h by paralysis of the hind limb. Rats exhibiting neurological deficits, including paralysis or motor function impairment were excluded from the study and euthanized immediately.

Plantar incision. The rat model of incisional pain was performed according to a previously described procedure (26). In brief, rats (weight, 250-280 g) were anesthetized with sevoflurane (3.0% for induction, 1.0% for maintenance) via a nose mask. A 1-cm longitudinal incision was made through the skin, fascia and muscle of the right hind paw, starting 0.5 cm from the proximal edge. The skin was sutured with 4-0 silk sutures after the underlying flexor muscle was divided. To avoid infection, an erythromycin ointment was applied to the incision.

Drug treatments. The rats were anesthetized with sevoflurane (3.0% for induction, 1.0% for maintenance) via a nose mask. Next, a 24-gauge over-the-needle Teflon catheter was inserted into the caudal vein and flushed with heparinized saline. The caudal vein catheter was used to infuse the experimental drugs. The control group (C) received saline infusion (0.1 ml/kg/min; 60 min), the remifentanil group (R) received remifentanil infusion (1.0 ml/kg/min; 60 min), the incision group (I) received a surgical incision, the remifentanil plus incision group (RI) underwent surgical incision and remifentanil infusion (1.0 ml/kg/min; 60 min), the remifentanil, incision and DOR agonist deltorphin II group (RD) received a surgical incision, remifentanil infusion (1.0 µg/kg/min i.v.; 60 min) and deltorphin II (10 µl of a 30 nM solution by intrathecal injection); and the remifentanil, incision and naltrindole group (RN) received a surgical incision, remifentanil infusion (1.0 µg/kg/min; 60 min) and naltrindole (10 µl of a 30 nM solution by intrathecal injection); n=12 per group.

In the patch clamp recording experiment, spinal slices from rat pups of the C group were incubated in artificial cerebrospinal fluid (ACSF) for 60 min. In the R group, spinal slices
were incubated in ACSF with 4 nM remifentanil for 60 min. In the RD group, spinal slices were incubated in ACSF with 4 nM remifentanil and 4 nM deltorphin for 60 min. Finally, in the RN group, spinal slices were incubated in ACSF with 4 nM remifentanil and 30 nM naltrindole for 60 min.

**Behavioral tests.** The paw withdrawal threshold (PWT) was measured using von Frey filaments (cat. no. BSEVF3; Harward Apparatus Co., Holliston, MA, USA) where the rats were placed in individual cages with a wire grid bottom. Each trial was repeated 5 times at 5-min intervals with a cut-off value of 60 g. The paw withdrawal latency (PWL) was measured using a hot plate (cat. no. YLS-6B; Zheng Hua Biological Instrument Co., Suixi, China). Each trial was repeated 5 times at 5-min intervals and a cut-off time of 20 sec to avoid tissue damage.

**Western blot analysis.** After drug treatment, rats were sacrificed by decapitation under sevoflurane anesthesia, and the lumbar enlargement of spinal cord (L3-L5) was immediately removed and stored at -80°C. To prepare a total lysate, the tissue was homogenized in ice-cold lysis buffer (2% Triton X-100, 150 mM NaCl, 50 mM Tris, 100 g/ml phenylmethylsulfonyl fluoride, 1 g/ml aprotinin and phosphatase inhibitors; pH 7.5). The lysate was centrifuged at 12,000 x g for 30 min at 4°C and the supernatant was used for a western blot analysis. To prepare membrane and cytosolic fractions, the tissue was separated into membrane, cytosolic and nuclear fractions by using a membrane, cytosolic and nuclear compartment protein extraction kit (cat. no. K3014005; Biochain Institute, Inc., Hayward, CA, USA). The protein concentration was measured using a Bio-Rad protein assay (cat. no. 5000006; Bio-Rad Laboratories, Inc., Hercules, CA, USA) and the samples were then heated to 99°C for 5 min. A total of 15 μg protein was loaded onto a 4-20% Criterion® Tris-HCl Protein Gel (cat. no. 3450032, Bio-Rad Laboratories, Inc.). The proteins then underwent electrophoresis and were transferred onto Immobilon® polyvinylidene difluoride membranes (cat. no. 1620177; Bio-Rad Laboratories, Inc.). All membranes were blocked in a buffer of 5% non-fat milk, 50 mM Tris-HCl, 154 mM NaCl and 0.05% Tween-20 (pH 7.4) for 1 h and subsequently incubated overnight at 4°C with antibodies directed against GluR1, phosphorylated-GluR1 (Ser845), PKA (all: 1:1,000 dilution; cat. nos. sc-7609, sc-24,593 and sc-28315, respectively. (all, Santa Cruz Biotechnology, Inc., Dallas, TX, USA), DOR (1:1,000 dilution; cat. no. ab63536; Abcam, Cambridge MA, USA) and β-actin (1:5,000 dilution; cat. no. A5316; Sigma-Aldrich; Merck KGaA, Darmstadt, Germany). The membranes were subsequently incubated with horseradish peroxidase-conjugated anti-mouse or anti-rabbit secondary antibodies (1:3,000 dilution; cat. nos. 115-035-003 and 111-035-003, respectively; Jackson Immuno Research Laboratories, Inc., West Grove, PA, USA) at room temperature for 2 h. They were then visualized using Clarity™ Western ECL Substrate (cat. no. 170-5060; Bio-Rad Laboratories, Inc.) and exposed on the ChemiDoc XRS System with Image Lab software (Bio-Rad Laboratories, Inc.). The intensity of the blots was quantified by densitometry using Image Lab software. β-actin was used as the loading control. The western blot analysis was repeated 3 times.

**Statistical analysis.** Statistical analysis was performed using SPSS 19.0 (IBM Corp., Armonk, NY, USA). Values are expressed as the mean ± standard deviation. Two-way analysis of variance (ANOVA) was used for the results of the behavioral tests and one-way ANOVA was used for the western blot analysis and whole-cell patch-clamp recordings, followed by post-hoc comparisons using the Tukey-Kramer test. P<0.05 was considered to indicate a statistically significant difference.

**Results**

**Remifentanil and incision-induced postoperative hyperalgesia model.** As in a previous study by our group (29), remifentanil treatment increased the sensitivity to heat pain and mechanical pain at the rate of 1 μg/kg/min from 2 to 48 h after discontinuation of remifentanil infusion. Remifentanil alone produced higher heat pain and mechanical pain sensitivity from 2 h to 5 days after remifentanil infusion. As presented in Fig. 1, thermal and mechanical hyperalgesia appeared at 2 h, reached a peak level on day 2 and persisted for 5 days after remifentanil infusion and/or incision (P<0.05). The results indicated that the effect of incision was about as high as that of remifentanil treatment regarding the induction of hyperalgesia, while there appears to be an enhancing effect in the RI group, which means remifentanil infusion and incision had an additive effect.

**Effect of remifentanil and incision on the expression of GluR1 in the spinal cord.** In a previous study by our group,
The membrane fraction of the GluR1 subunit reached a peak level on day 2 after remifentanil-induced postoperative hyperalgesia (30). Therefore, spinal cords (L1-L5) were harvested at 2 days after remifentanil infusion. As presented in Fig. 2, the expression of membrane GluR1 was increased in the remifentanil group and the incision group on day 2 (P=0.003 and 0.004, respectively). The membrane GluR1 in the RI group demonstrated a notable increase compared with the R and I groups. However, no change in the expression of total GluR1 was detected in all groups (P>0.05 for each). The ratio of membrane and total GluR1 was increased in the remifentanil and the incision group on day 2 (P=0.009 and 0.002, respectively). The ratio of membrane and total GluR1 in RI group demonstrated a notable increase compared with the R and I groups. These results suggested that remifentanil infusion or/and incision promoted GluR1 membrane trafficking in the spinal cord. Remifentanil infusion and incision had an additive effect on promoting GluR1 membrane trafficking.

**Membrane insertion of DOR is increased in the spinal cord of rats with remifentanil and incision-induced hyperalgesia.** Spinal cords (L1-L5) were separated at 2 days after remifentanil infusion. Compared with that in the control group, the membrane fraction of DOR exhibited a significant increase after remifentanil infusion and incision. Spinal cords (L1-L5) were separated at 2 days after remifentanil infusion. (A) Representative western blots displaying m-DOR and t-DOR protein levels in the spinal cords. β-actin was used as a loading control. (B) Bar graph displaying quantified protein levels. m-DOR was increased in the R, I and RI groups on day 2. Values are expressed as the mean ± standard deviation (n=8). *P<0.01 compared with C group. Groups: C, control group; R, remifentanil group; I, incision group; RI, remifentanil plus incision group. m-DOR, δ opioid receptor in the membrane; t-DOR, total DOR.
remifentanil infusion and/or incision, whereas total protein levels of DOR were not affected (P<0.01; Fig. 3). The ratio of membrane to total DOR increased in the remifentanil and the incision group on day 2 (P=0.007 and 0.003, respectively). The membrane DOR expression in the RI group demonstrated a notable increased compared with the R and I groups. The ratio of membrane to total DOR also significantly increased compared with the R and I groups. Together, these results suggested that remifentanil infusion and/or incision promoted DOR membrane trafficking in the spinal cord. Remifentanil infusion and incision had an additive effect on promoting DOR membrane trafficking.

**DOR antagonist naltrindole attenuates remifentanil and incision-induced postoperative thermal and mechanical hyperalgesia.** The selective DOR agonist deltorphin or the antagonist naltrindole were used to investigate whether DOR participates in remifentanil-induced postoperative hyperalgesia. Compared with that in the RI group, the DOR agonist deltorphin had no effect on either mechanical or thermal hyperalgesia. However, it was observed that DOR antagonist naltrindole significantly decreased remifentanil-induced increases in PWT and PWL (P<0.05; Fig. 4). The anti-hyperalgesic effect of naltrindole was demonstrated in the rat model of remifentanil-induced postoperative hyperalgesia. These results suggested that inhibition of DOR had an anti-hyperalgesia effect in the remifentanil and incision-induced hyperalgesia model.

**DOR inhibition decreases membrane insertion of GluR1 in rats with remifentanil-induced hyperalgesia.** Compared with that in the control group, the expression of membrane GluR1 increased in dorsal horn neurons in the remifentanil and incision group (P=0.0009). The membrane GluR1 expression levels were not significantly different between the RI group and the RD group. Naltindole treatment inhibited remifentanil and incision-induced increases in mGluR1 and the m/t GluR1 ratio (P=0.0013, 0.0022). However, no change in total protein levels of GluR1 was observed in all groups (P=0.463; Fig. 5). The increased ratio of membrane to total GluR1 was restored with naltrindole treatment (P=0.0065 and 0.0035). These results suggested that DOR inhibition alleviated GluR1 membrane insertion in rats with remifentanil and incision-induced hyperalgesia.

**DOR is required for remifentanil enhanced AMPAR-mediated increases in the mEPSC in dorsal horn neurons.** To examine
the role of DOR in the function of AMPAR in spinal cord neurons, whole-cell patch-clamp recordings were made in the presence of remifentanil to detect the changes in the AMPAR-mediated mEPSC. Representative traces of AMPAR-mediated mEPSCs (scale bar, 100 pA, 30 sec) are presented in Fig. 6A. Incubation with remifentanil significantly increased the amplitude of AMPAR-mediated mEPSCs while decreasing the inter-event interval of AMPAR currents. Naltrindole and remifentanil decreased changes in the amplitude and the frequency of the AMPAR current. Values are expressed as the mean ± standard deviation (n=8). *P<0.01 compared with C group. Groups: C, control group; R, remifentanil group; RD, remifentanil and DOR agonist deltorphin group; RN, remifentanil and DOR antagonist naltrindole group. AMPAR, α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor; DOR, δ opioid receptor; mEPSC, miniature excitatory postsynaptic current.

Figure 6. Naltrindole inhibits remifentanil-enhanced AMPAR-mediated enhancement of mEPSCs in dorsal horn neurons. (A) Representative traces of AMPAR mEPSCs (scale bar, 100 pA, 30 sec). (B and C) Remifentanil incubation significantly increases the amplitude of AMPAR-mediated mEPSCs while decreasing the inter-event interval of AMPAR currents. Naltrindole and remifentanil decreased changes in the amplitude and frequency of the AMPAR current. Values are expressed as the mean ± standard deviation (n=8). *P<0.01 compared with C group. Groups: C, control group; R, remifentanil group; RD, remifentanil and DOR agonist deltorphin group; RN, remifentanil and DOR antagonist naltrindole group. AMPAR, α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor; DOR, δ opioid receptor; mEPSC, miniature excitatory postsynaptic current.

Figure 7. DOR activation significantly increases the phosphorylation of GluR1 at Ser845 and PKA in the spinal cords of rats with remifentanil-induced postoperative hyperalgesia. Spinal cords (L1-L5) were separated at 2 days after remifentanil infusion. (A) The pGluR1 (Ser845) and PKA were measured by western blot analysis. β-actin was used as a loading control. (B) Quantification of the blots indicated that remifentanil infusion and incision increased the phosphorylation of GluR1 at Ser845 and PKA, and this increase was inhibited by naltrindole. Values are expressed as the mean ± standard deviation (n=8). *P<0.01 compared with C group. Groups: C, control group; RI, remifentanil plus incision group; RD, remifentanil, incision and DOR agonist deltorphin group; RN, remifentanil, incision and DOR antagonist naltrindole group. DOR, δ opioid receptor; pGlu, glutamate receptor; PKA, protein kinase A.

Discussion

In the present study, the thermal and mechanical hyperalgesia was increased in a rat model of remifentanil and incision-induced hyperalgesia, which was partly restored through treatment with naltrindole. Furthermore, the membrane insertion of the DOR and GluR1 subunits was enhanced with the application of remifentanil.
of remifentanil in the spinal cord, and this was reversed by the presence of naltrindole. The whole-cell patch clamp recording results suggested that the frequency and amplitude of AMPAR-mediated mEPSCs increased in the presence of remifentanil; however, the enhanced AMPAR function was reversed by naltrindole. The present findings suggested that naltrindole inhibited the remifentanil-induced hyperalgesia effect, possibly by inducing DOR and GluR1 internalization from the synaptosomal membrane into the neuronal cytosol, thereby reducing AMPAR function in the spinal cord.

The present study demonstrated that naltrindole, a selective DOR inhibitor, reduced remifentanil-induced mechanical and thermal hyperalgesia, indicating that DOR may be involved in pain signal transmission and responses. Several studies indicated that the membrane trafficking of DOR increased in vivo and in vitro in morphine-tolerant mice, indicating that membrane insertion of DOR has an important role in opioid-induced tolerance and hyperalgesia (31,32). Other studies demonstrated that the high sensitivity to opioid-induced mechanical and thermal pain was prevented with the application of naltrindole, suggesting that naltrindole may be a potential anti-hyperalgesic agent for treating OIH (24,33).

The subunit composition and number of synaptic AMPARs are not static. The function of AMPARs is dependent on the composition of AMPAR subunits (34). Co-expression of GluR1 and GluR3 or GluR4 is required for the formation of fully functional channels, which are Ca²⁺-permeable, while homomeric GluR2 channels have no function with little Ca²⁺-permeability (35). GluR1 subunits are the principal subunits responsible for AMPAR channel activity, and are highly expressed on the neuronal synaptic membranes in the superficial dorsal horn (36). The expression levels of GluR1 are reasonable for assessing the function of AMPAR. The present results suggested that remifentanil infusion affects the membrane trafficking of GluR1; however, there are no significant changes in GluR2 expression. Activation of Ca²⁺-permeable AMPARs in dorsal horn neurons enhances AMPAR-mediated synaptic transmission (30). The results of the present study supported the involvement of GluR1 trafficking in spinal sensitization and pain behavior. In dorsal horn neurons, application of DOR inhibitor naltrindole apparently inhibited the accumulation of GluR1 in the plasma membrane fraction. This indicated that remifentanil-induced hyperalgesia promoted synaptic delivery of GluR1-containing AMPARs in a DOR-dependent manner.

A previous study reported that the GluR1 subunit in dorsal horn neurons was phosphorylated at the Ser845 residue following neuropathic pain. The phosphorylation of Ser845 in GluR1 by PKA regulates the open channel probability of AMPARs (37). The membrane insertion of GluR1 depends on the phosphorylation of GluR1 at Ser845 by PKA (38,39). A previous study reported that phosphorylation of GluR1 at Ser845 was increased in inflammatory pain, which was mediated by the activation of PKA (40,41). In the present study, it was demonstrated that DOR increased the phosphorylation of the GluR1 subunit of AMPARs at Ser845 alongside increases of PKA expression in rats with remifentanil-induced hyperalgesia.

The present study indicated that inhibition of DOR abolished the hypersensitivity to thermal and mechanical pain during remifentanil-induced postoperative hyperalgesia development and maintenance. DOR activation increased the expression of AMPAR subunit GluR1 and the function of AMPARs by altering pGluR1 levels in the spinal cord. Although the mechanism of OIH remains to be fully elucidated, DOR appears to be a novel target for preventing and treating remifentanil and incision-induced hyperalgesia.
